

How do I run a regression using the ADD Health in STATA?

You have to have assigned the appropriate weights, strata and psus.

svyset [pweight=gswt1],strata(region) psu(psucid)

This example is for the cross sectional wave 3 data.

The regression syntax is as follows for survey logistic regression:

svylogit depvar ivar1 ivar2 ivar3, subpop(female)

This regression is specific to the subpopulation of females, remember, you when using the Add Health you can't just take out the whites and still have the correct standard errors.
