

### **How do I run a weighted frequency with the ADD Health data?**

Currently, svytab must have two variables, not just one. So what you need to do is generate a variable that has a value of only one so that your cross tab comes out correctly. Here is what you do.

```
gen newvar =1
```

This makes a variable called 'newvar' that equals one for every case.

```
svytab newvar bio_sex3
```
